

## Chinese Remainder Theorem

Let's say we have a system of congruences like this:

$$\begin{aligned}x &\equiv 0 \pmod{m_1} \\x &\equiv 1 \pmod{m_2} \\x &\equiv 2 \pmod{m_3}\end{aligned}$$

and so on...

CRT tells us that if all the moduli  $m_1, m_2, \dots$  are pairwise coprime (i.e.  $\gcd(m_i, m_j) = 1$  for all  $i \neq j$ ),

then there exists a unique solution modulo  $M = m_1 m_2 \dots m_n$ .

That means there's exactly one number between 0 and  $M-1$  that satisfies all those congruences.

Let's Recall :-

$$\begin{aligned}x &\equiv a \pmod{n} \\&(\text{read as "x is congruent to a modulo n"}) \\&\Rightarrow n \mid (x - a) \quad [\text{i.e. } n \text{ divides } (x-a)] \\&\Rightarrow x \text{ and } a \text{ have the same remainder when dividing by } n\end{aligned}$$

You'll often see equations like:  
 $x \equiv 3 \pmod{5}$   
which means all numbers that give remainder 3 when divided by 5:  
So the set of all possible  $x$  is:  
 $\{a + kn \mid k \in \mathbb{Z}\}$   
That is,  $x \equiv a + kn$

Eq:-  
 $x \equiv 2 \pmod{3}$   
 $x \equiv 3 \pmod{5}$   
 $x \equiv 2 \pmod{7}$

equation 1  $\rightarrow x \equiv 2 \pmod{3}$   
 $x \equiv 2 + 3k \rightarrow 2, 5, 8, 11, 14, 17, 20, 23, 26, 29, 32, \dots$

equation 2  $\rightarrow x \equiv 3 \pmod{5}$   
 $x \equiv 3 + 5k \rightarrow 3, 8, 13, 18, 23, 28, 33, 38, 43, 48, \dots$

equation 3  $\rightarrow x \equiv 2 \pmod{7}$   
 $x \equiv 2 + 7k \rightarrow 2, 9, 16, 23, \dots$

so, 23 is the smallest integer to satisfy all the congruences

Now, we can say that next integer to satisfy will be

$$23 + \text{LCM}(3, 5, 7)k$$

And since 3, 5, 7 are co-prime then LCM is just  $3 * 5 * 7$

$$= 23 + 105k$$

$$\Rightarrow x \equiv 23 \pmod{105}$$

But we need a better way to solve this so now let's look at this mathematically

CRT says that if all the moduli are pair-wise coprime then a unique solution exist modulo  $M$  ( $m_1 * m_2 * \dots * m_n$ )

Proof:-

$$\text{We have, } x \equiv a_1 \pmod{m_1}$$

$$x \equiv a_2 \pmod{m_2}$$

$$\vdots$$

$$x \equiv a_n \pmod{m_n}$$

Let,  
 $M = m_1 * m_2 * m_3 \dots m_n$

$$\text{and, } M_i = M / m_i$$

Note:

$$\gcd(M_i, m_i) = 1$$

st:

$$M_i x_i + m_i j_i = 1 \quad \{ \text{By Bezout's Identity} \}$$

By reducing the equation we get,

$$M_i x_i \equiv 1 \pmod{m_i}$$

Now, multiplying by  $a_i$  on both sides we get,

$$(M_i a_i) x_i \equiv a_i \pmod{m_i}$$

Set,  
 $x = M_1 a_1 x_1 + M_2 a_2 x_2 + \dots + M_n a_n x_n$

Observation:

$$M_i \equiv 0 \pmod{m_j}, i \neq j$$

$M_i$  has no reason to be 0 mod  $m_j$  (since  $\gcd(M_i, m_j) = 1$ )

Fix,  
We do this using a modular inverse.

$$\text{inv} \equiv M^{-1} \pmod{m_i}$$

This means,

$$M_i * \text{inv} \equiv 1 \pmod{m_i}$$

Therefore,

$$x \equiv \text{modular inverse of } m_i$$

Now we can say,

$$x \equiv M_1 a_1 x_1 \pmod{m_1}$$

$$x \equiv M_2 a_2 x_2 \pmod{m_2}$$

This is how we prove that a solution exist

Now let's proof that the solution is unique

Proof:-

We already have a solution  $x$

Suppose  $y$  is another solution, then we can say

$$\begin{aligned}x &\equiv a_1 \pmod{m_1} & y &\equiv a_1 \pmod{m_1} \\x &\equiv a_2 \pmod{m_2} & y &\equiv a_2 \pmod{m_2} \\&\vdots &&\vdots \\x &\equiv a_n \pmod{m_n} & y &\equiv a_n \pmod{m_n}\end{aligned}$$

Subtracting both the equations we get

$$(x - y) \equiv 0 \pmod{m_1}$$

$$(x - y) \equiv 0 \pmod{m_2}$$

$$\vdots$$

$$(x - y) \equiv 0 \pmod{m_n}$$

This implies:

$$(x - y) \mid m_1$$

$$(x - y) \mid m_2$$

$$\vdots$$

$$(x - y) \mid m_n$$

$$\Rightarrow (x - y) \mid M$$

$$\Rightarrow x \equiv y \pmod{M}$$

This proves that  $x$  and  $y$  are in the same equivalence class

Final solution:

$$x \equiv \sum_i a_i M_i \text{ inv}_i \pmod{M}$$

So, we will simply calculate  $M$  and inverse then using the above formula we will get our  $X$

Example:-

An old woman goes to market and horse staps in her basket and carries the eggs. The rider affects to her and she lost one egg. When she took two at a time, there was one egg left. She does not remember the exact number, but when she had taken them out two at a time, there was one egg left. The same happened when she picked 3, 5, 7 eggs at a time, but when she took seven at a time they came out even. What is the smallest number of eggs she could have had?

Let's rephrase it in mathematical notations.

Suppose, the old woman had  $x$  eggs in her basket.  
Now she claims that when she took out egg from the basket 2 at a time, she had one egg left.

The rider affects to her and she lost one egg. When she took two at a time, there was one egg left.

She does not remember the exact number, but when she had taken them out two at a time, there was one egg left.

The same happened when she picked 3, 5, 7 eggs at a time, but when she took seven at a time they came out even.

What is the smallest number of eggs she could have had?

Let's rephrase it in mathematical notations.
